Day 37 — Mapping Text Functions

* When ever you are using a string for every character you will have index like index, Substring, length

eg:

P	A	V	A	N	C	H	E	M	M	A → String
0	1	2	3	4	5	6	7	8	9	10 → Index

Now Index(2) → what

eg: When is the occurence of A or C or E you want to know at which index that particular character is coming

for that we will use index of

index of(2) ⇒ (V) = 2

(E) = 7

* from the first position where exactly the first occurence is happening → indexof(--)

* Case Sensitive

→ Here the most important thing we need to remember

***

indexof(2) ⟶ first occurence character

lastindex(2) ⟶ last occurence of that character

PAVAN CHEMMA
0 1 2 3 4 5 6 7 8 9 10

index(2) → m → 8 | index(2) → A → 1

lastindex(2) → m → 9 | lastindex(2) → A → 3

* indexof(3) → There won't be any difference bet-ween index of (2) & index of (3)

Only IndexOf(3) → has 3 inputs

indexOf(3)

Main String ⟵ String pattern index

* lastIndexof(3)

Before starting with node functions we need to discuss about the context handling

→ Context handling is most important
