Day 52

APIM Part (1)

* Jms Adapter, guarantee message delivery, Retry machanism
  *** most important → it is interview Question's
  how you will proces Retry machanism in SAP CPI
  Ans: we need to use the Jms adapter
* If we want to create, Secure, manage any API's we will use Api management.
* What is an API → for Example → if we want to connect to any System we will use Api
  eg: different way's will be there to connect the Systems → SFTP, HTTP, Queues, (API)
* endpoint URL ⟶ SOAP API
  API Rest API,
  OData API
* Suppose if you want to connect with API Based Connects then API Based Connects we will Called as
* file Based Interface or queue Based Interface we are Connecting it will be like a real time integration

* Suppose → File placed → Target System → Scheduling.

* Source → SFTP → file placed → Scheduled time the file's will be picked.

near real time → nothing But → Scheduled time The file's will be picked.

* But Real time → API management

*** → If we want to go with Real time Integration's then we will use API management Service

* legacy → Real time integration (X)
→ Near time integration (✓) (Scheduling)

*eg: Old Time → money transfer → goto Bank → cash deposit Reciept → manually deposit

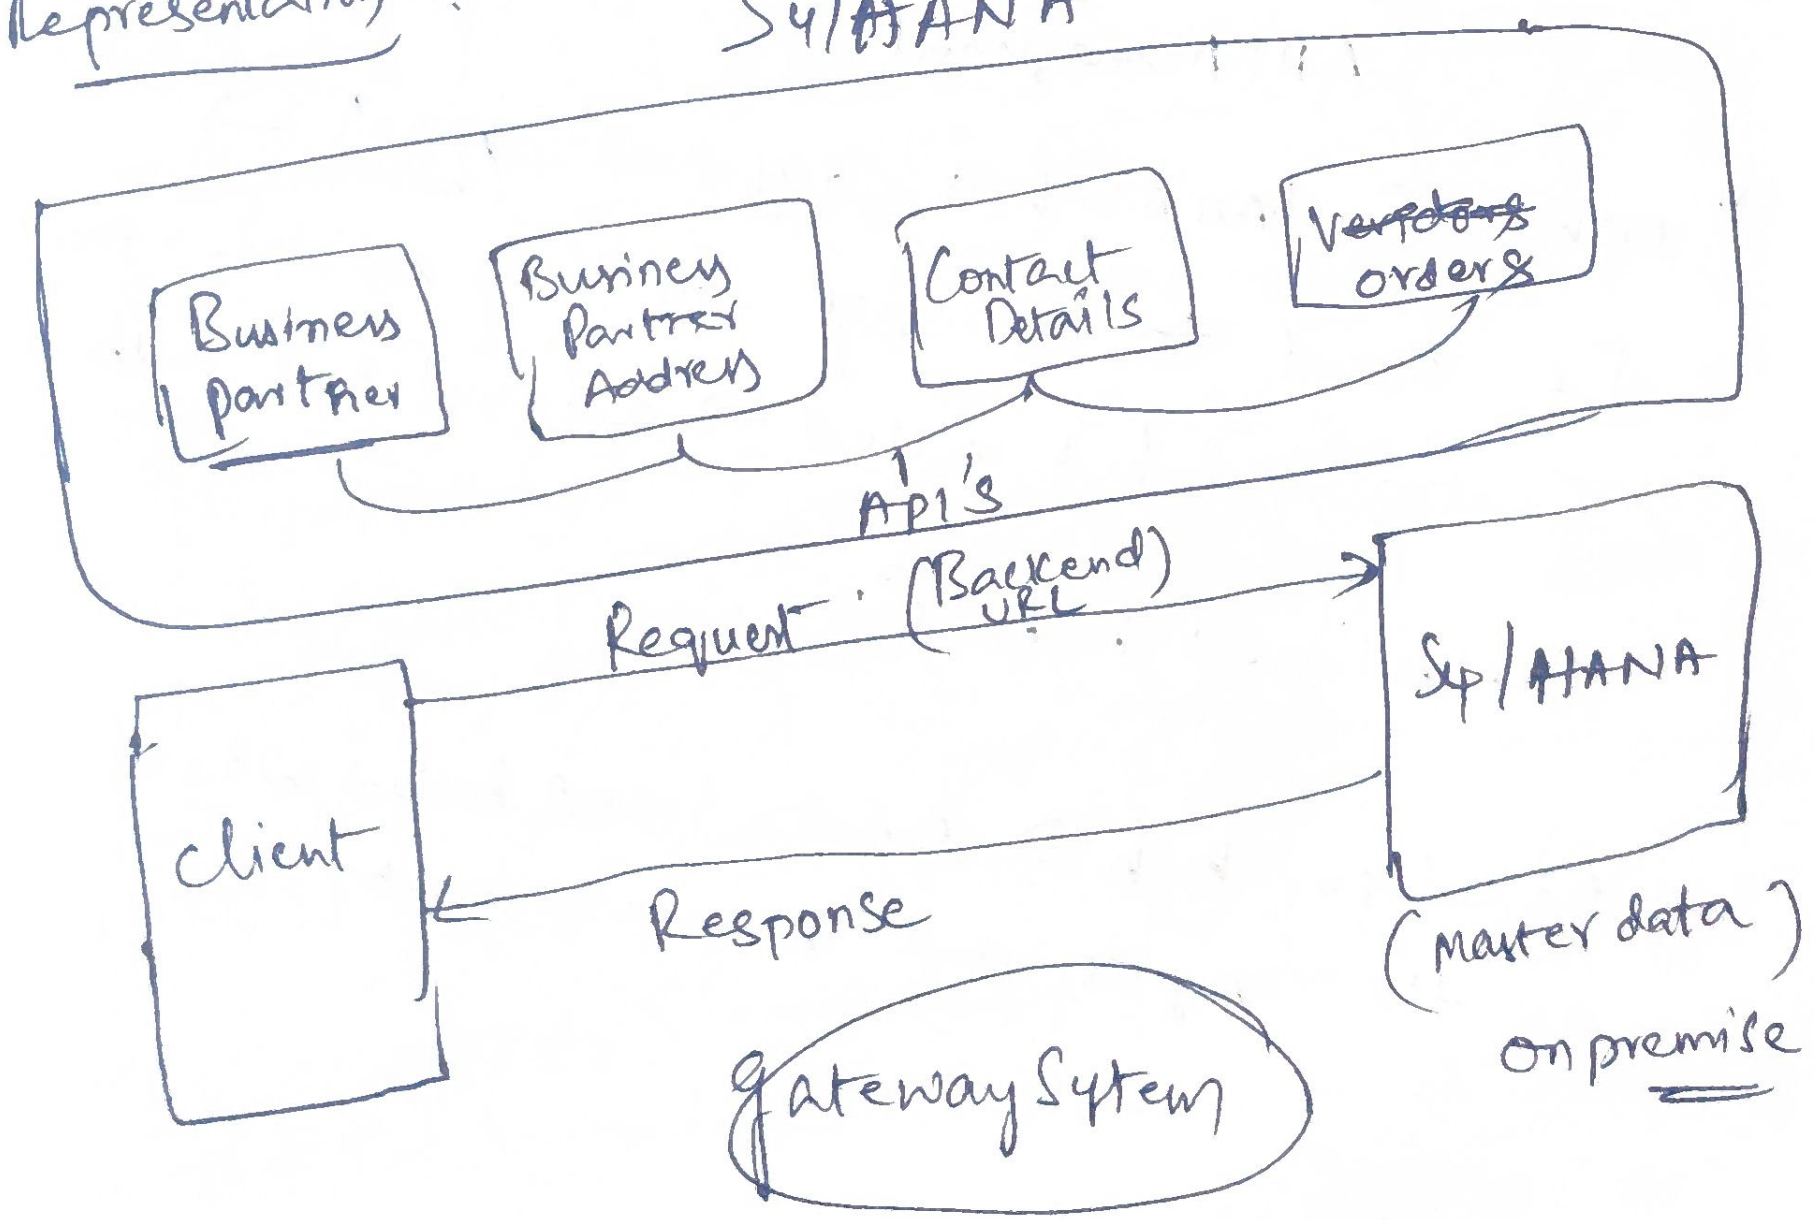

* Now, Digital platform

eg: UPI transactions
gpay, phonepay, etc.

*eg: Amazon → order's information → my orders →
get → get all orders → Backend system
→ fetch → display → frontend

⇒ Backend System → S/4 HANA (SAP ERP System)

Representation : S4/HANA

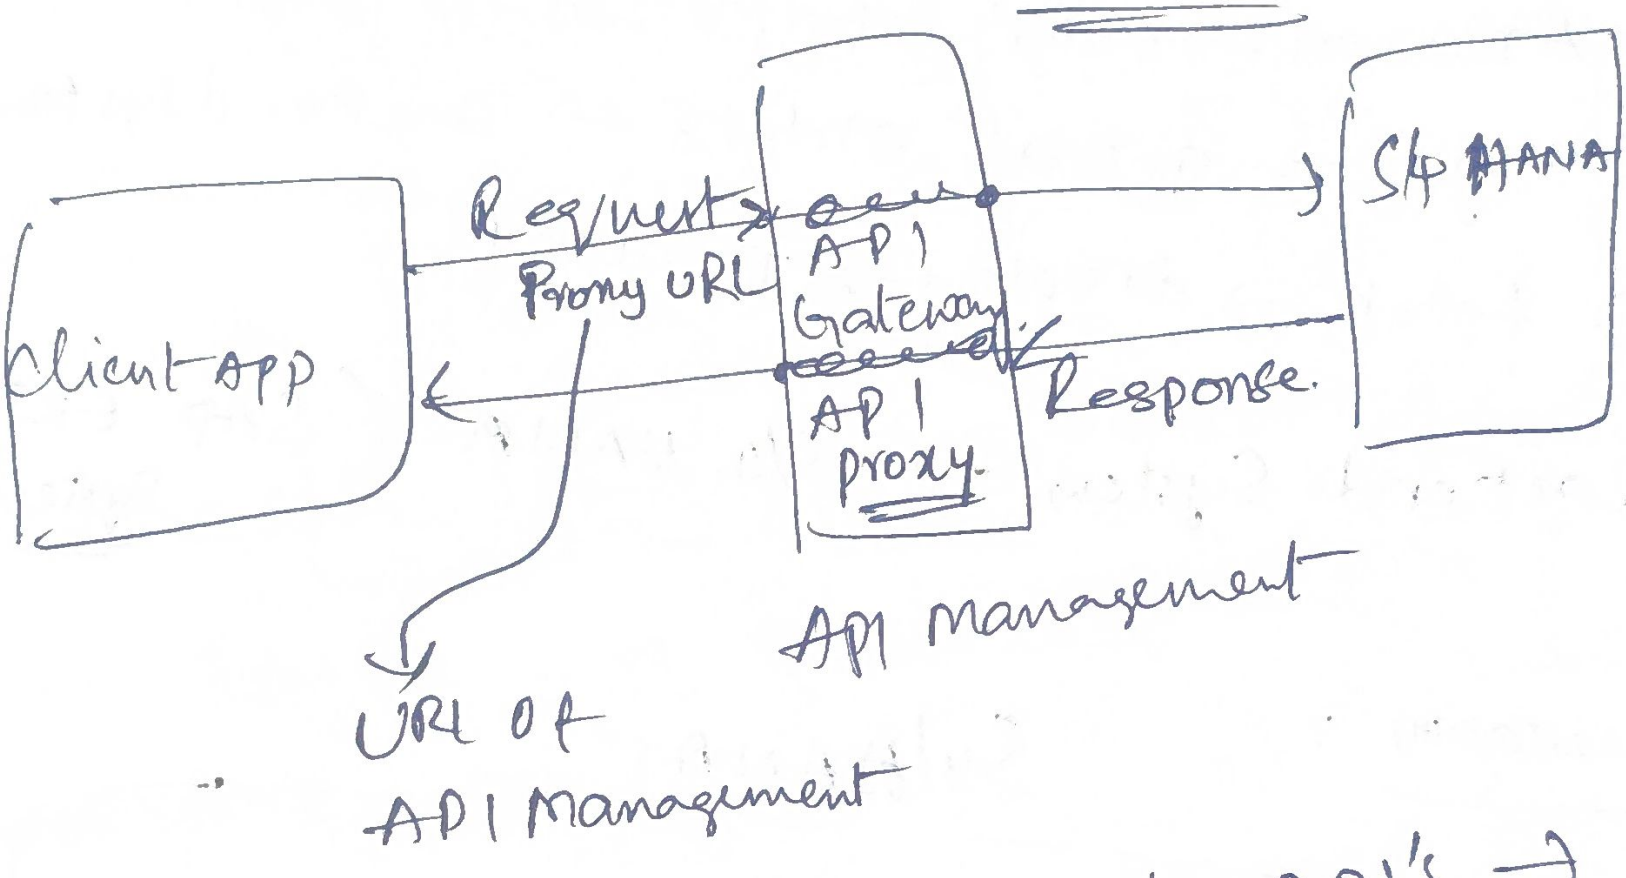

gateway System → API management

* load balancer → Sequential

eg: 10,000 calls → S4/HANA

load Balancer

* NOW S4/HANA has different APIs → If want to manage all those APIs → that Centralized hub called → centralized hub

Centralized hub :C

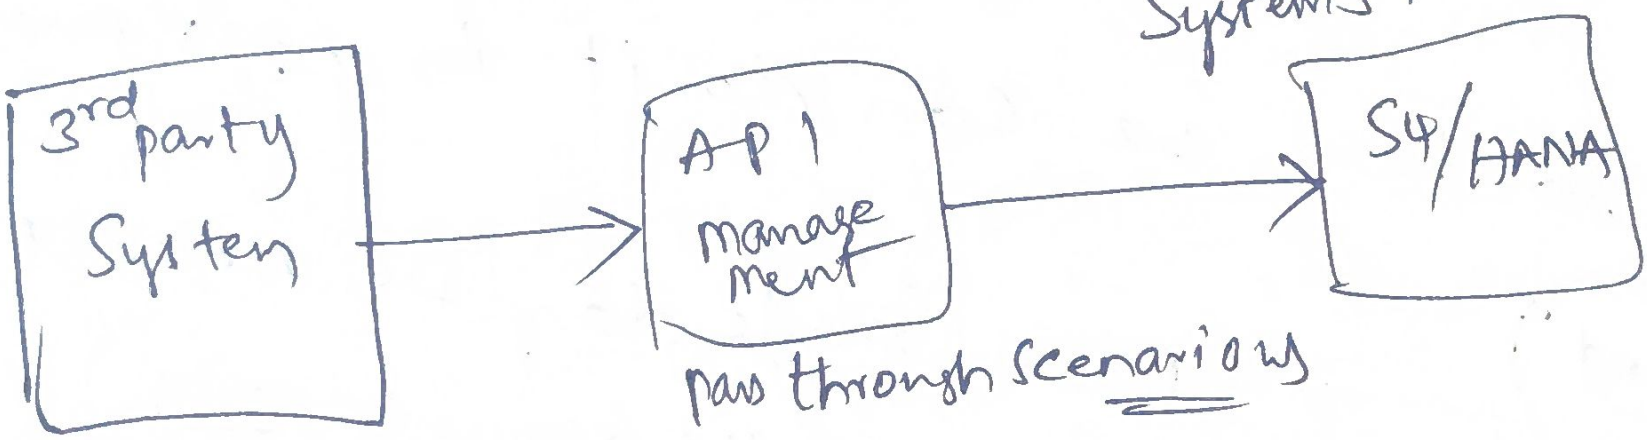

* Developer hub → Centralized hub → where all the Api's are management

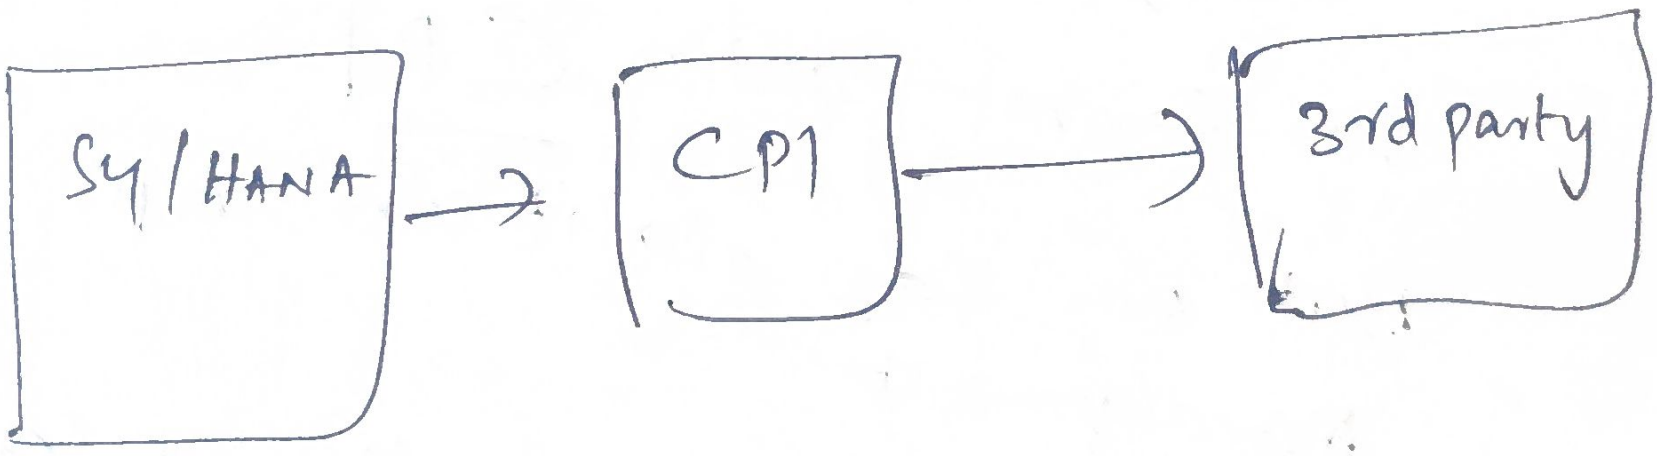

* API Gateway: Instead of giving the our backend URL to the Third party System we will give API gateway proxy URL

* Suppose → 1 area → 2 houses → which house you want to secure → own house

* Real time Scenarios, (Digital platforms) → Internal Systems will be secured first

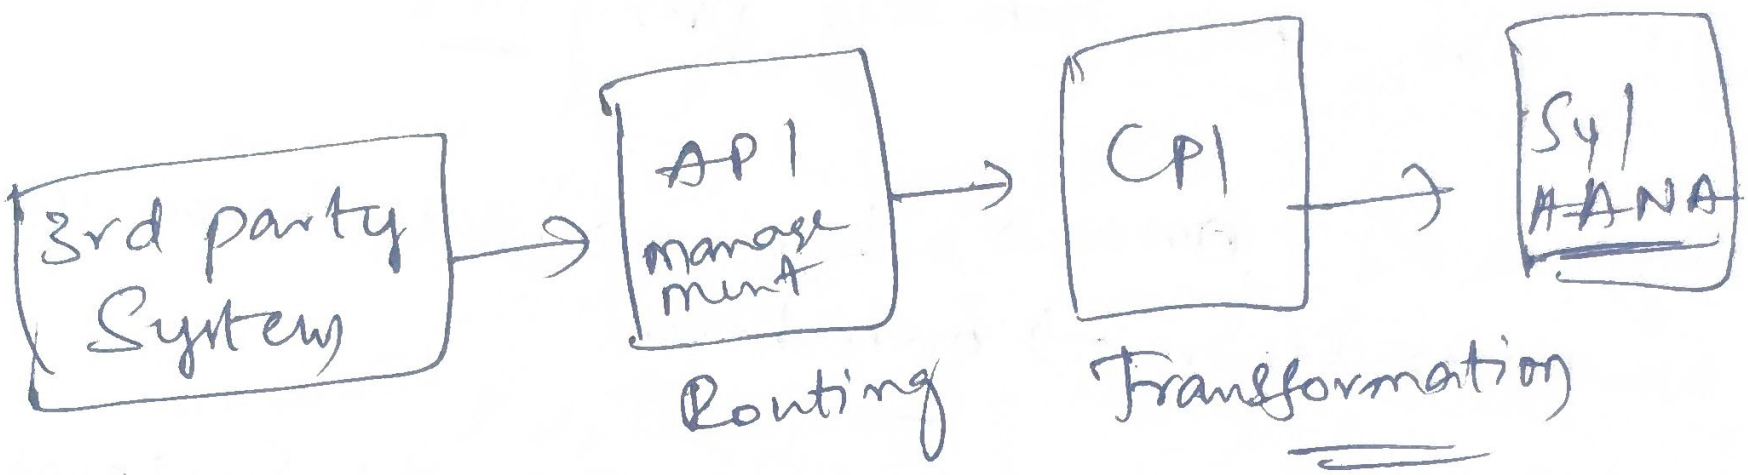

Instead other System's.

* passthrough Scenarios → you are trying to get the data from S4/HANA and sending that data as it-is We will use API Management

* any transformation is needed then we will use CPI in between

* Question: Suppose, Restriction of ip address in CPI "NO"

So here we can do it in API management

2nd → in a single day we need to accept 100 requests only ;

We cannot do it in CPI

But we can do it in API management

* API management → passthrough scenarios "not" for mapping or transformation

* Why we exactly use API management

Secure, manage, Routing

* API management is an optional approach

* is there any other advantage ~~is~~

→ you can create document for API proxy

eg: Assume → API call → orders (S4/HANA)

CPI → options (many) → message monitor logs →

get any message logs →
